# E-commerce sales & product dashboard

Illustrative sample data for a fictional store — not actual store performance.

## What this 30-day view covers

- Rolling 30-day sales and order health
- Weekly sales momentum and conversion signals
- Top products, refunds, channels, and sample actions

## How to read the story

Start with the topline, then look for the drivers behind it: weekly momentum, product mix, channel quality, and customer-friction signals.

All figures are fictional and intended only to demonstrate a dashboard-reading workflow.

# 30-day sales snapshot

Illustrative sample data for a fictional store.

| NET SALES | ORDERS | AVERAGE ORDER VALUE | STORE CONVERSION | REFUND RATE |
|---|---|---|---|---|
| $44.5K | 1,126 | $39.52 | 2.8% | 3.1% |

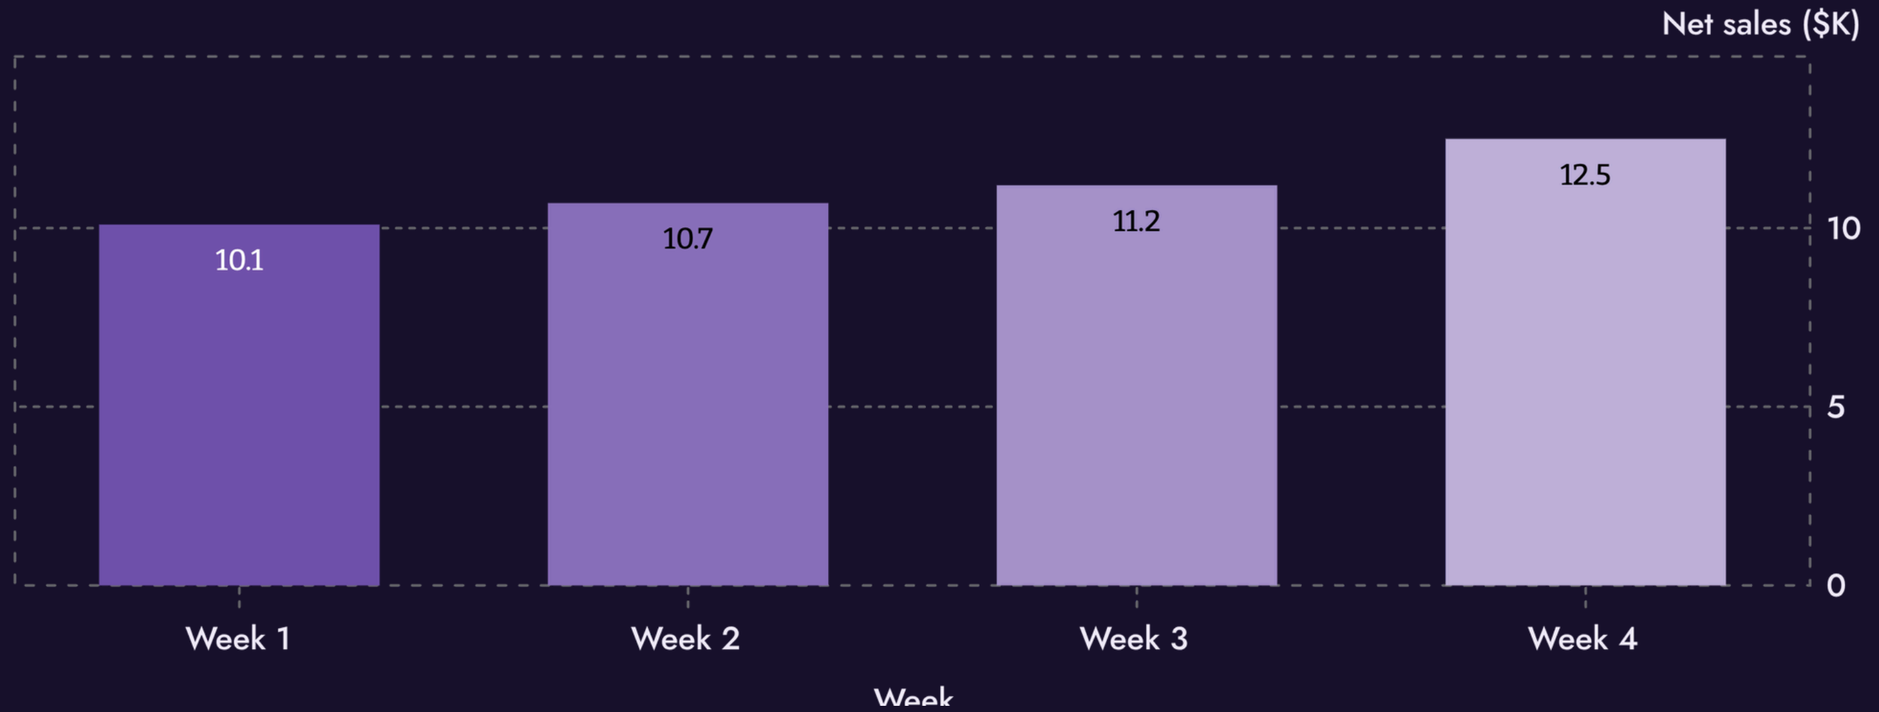

## What the snapshot says

The sample math is internally consistent: $44.5K divided by 1,126 orders is about $39.52 per order. The 2.8% conversion rate and 3.1% refund rate frame the next questions around acquisition quality and post-purchase friction.

Read these as connected signals, not standalone performance judgments; traffic mix, product category, and measurement definitions would need validation.

# Weekly net sales momentum

Illustrative sample data — fictional weekly totals in $K.

## Takeaway: steady upward sample momentum

Sales increase every week, from $10.1K to $12.5K. That is a transparent $2.4K lift, or about 23.8% from Week 1 to Week 4; the final week is also the strongest at $12.5K.

This pattern supports a question, not a conclusion: was the lift driven by demand, promotion, timing, or mix? The demo data does not identify the cause.
Sample readout: sales rose each week, with the final week strongest.

# Orders & conversion signals

Illustrative sample data for a fictional store — directional, not actual performance.

1,126

COMPLETED ORDERS

Sample 30-day order count.

2.8%

STORE CONVERSION

Sample visit-to-order rate.

## Interpretation to carry into discussion

Orders show the outcome; conversion adds a possible efficiency lens. A 2.8% sample conversion rate means the next useful cut would be traffic by channel, device, campaign, and landing page—not a blanket verdict on performance.

Because the demo provides no visits, period comparison, or funnel steps, it cannot show whether the rate is improving or where friction occurs.

# Top products by net sales

Illustrative sample data; rankings are fictional.

| Product | Net sales | Units | Rank |
|---|---|---|---|
| **Insulated Bottle** | $12.8K | 299 | First |
| **Trail Pack** | $9.0K | 180 | Second |
| **Coffee Tumbler** | $6.7K | 335 | Third |

## Takeaway: revenue leadership differs from unit leadership

The Insulated Bottle leads the listed products on sample net sales at $12.8K, while the Coffee Tumbler sells the most units at 335. Across these three products, the table shows $28.5K and 814 units; the Bottle contributes about 44.9% of listed sales, while the Tumbler contributes about 41.2% of listed units.

These are calculations within the three displayed products only—not a claim about the full catalog or actual demand.

Sample observation: the Bottle leads revenue while the Tumbler leads units.

# Product mix: revenue vs. units

Illustrative sample data for a fictional store.

INSULATED BOTTLE

$12.8K

299 units

Highest sample revenue.

TRAIL PACK

$9.0K

180 units

Sample mid-tier contributor.

COFFEE TUMBLER

$6.7K

335 units

Highest sample unit volume.

## Read the mix in two dimensions

Bottle leads sample revenue ($12.8K; 299 units), while Tumbler leads units (335) but has the lowest revenue ($6.7K). Revenue per listed unit: Bottle ~$42.81, Trail Pack $50.00, Tumbler $20.00.

Descriptive ratios only—not prices or margins; discounts, bundles, and costs are unknown.

Illustrative interpretation: unit velocity and revenue contribution can point to different merchandising moves.

# Refund health check

Illustrative sample data — fictional rate, not an actual store metric.

REFUND RATE

## 3.1%

Sample share of orders refunded.

## Questions to investigate

- Which products generate the most refunds?
- Are size, quality, or delivery issues concentrated?
- Can product detail pages set clearer expectations?

## What this metric can—and cannot—say

A 3.1% sample refund rate is a signal to segment, not a diagnosis. With 1,126 sample orders, a rough translation would be about 35 refunded orders if the rate is applied directly, but the deck does not define timing, eligibility, or whether refunds are order- or item-based.

The responsible next step is to compare refund reasons and products against the same measurement window.

No operational conclusion should be drawn from this fictional example.

# Sample channel scorecard

Illustrative sample data for a fictional store; channel values are demo-only.

| Channel | Orders | Conversion | Readout |
| --- | --- | --- | --- |
| Organic search | 420 | 3.4% | Efficient sample driver |
| Paid social | 310 | 2.1% | Volume opportunity |
| Email | 246 | 4.6% | Strongest sample rate |
| Direct | 150 | 2.7% | Steady sample base |

## Takeaway: volume and efficiency are different lenses

The four displayed channels sum to all 1,126 sample orders. Organic search contributes the most orders at 420, while email shows the highest sample conversion at 4.6%—2.5 percentage points above paid social's 2.1%. That contrast makes this a useful diagnostic view, not a spend-reallocation instruction.

The table does not show visits, costs, attribution rules, or statistical confidence, so channel quality cannot be concluded from these figures alone.

Demo figures are not a recommendation to reallocate real spend.

# Illustrative opportunities to test

These are example hypotheses based on fictional sample data.

## Merchandising

Bundle the Insulated Bottle with complementary accessories.

**Why test:** It leads the displayed products on sample revenue.

## Conversion

Test clearer delivery and returns messaging at checkout.

**Why test:** The sample funnel view shows a 2.8% store conversion rate and a 3.1% refund rate, both needing real-data context.

## Retention

Use the sample email signal to test replenishment reminders.

**Why test:** Email has the highest displayed sample conversion at 4.6%, but the deck does not prove causation or repeat behavior.

## Make each hypothesis measurable

For a real test, define one success metric, a comparison group, a fixed window, and guardrails such as refunds or margin. This demo supplies prompts for discussion, not enough evidence to prioritize one action.

# Dashboard takeaways

Illustrative sample data for a fictional store — not actual store performance.

1. Sample net sales total $44.5K across 1,126 sample orders, implying an average order value of about $39.52.
2. Sample weekly sales rise every week from $10.1K to $12.5K—a $2.4K, or roughly 23.8%, increase across the displayed window.
3. The Insulated Bottle leads sample revenue at $12.8K, while the Coffee Tumbler leads sample units at 335; revenue leadership and unit leadership differ.
4. The displayed channel rows reconcile to 1,126 sample orders; email has the highest sample conversion at 4.6%, while organic search has the most sample orders at 420.
5. Sample refund rate is 3.1%, a prompt to inspect reasons and product concentration—not a conclusion about store health.

## Presenter close

The dashboard demonstrates how to move from a headline to a testable question: confirm the definitions, segment the drivers, and replace every demo figure with verified data before making a decision.
